A passionate Research Engineer with over 5 years experience in research and development.

## Work Experience

Hitachi India R&D (2015 - Present)

- Smart city analytics
- Cybersecurity (Vulnerability Risk Management)
- Cloud Platform (Upstream technical contributor to Openstack, log monitoring, Federated authentication etc.)

## Education

Bachelor of Engineering in Computer Science

## Interests

Travelling, Cooking and food photography

## Contact Information

[sanjana@hitachi.co.in](mailto:sanjana@hitachi.co.in)

4. Methodology
5. Results and Discussion
6. Conclusion and Future Work

## Background

- Cities are facing massive issues related to environment, living conditions and medical facilities with rapid urbanization.
- India's urban population is expected to grow from 410 million in 2014 to **814 million** by 2050.\*

- Smart cities need to solve the problems of Urbanization.
- **Environmental conditions** of the city need to be assessed and prioritized.
- **Medical facilities** in the cities has to be improved to provide better quality of life to citizens.
- Cities have to be **self sufficient** to handle situations like the pandemic.

Lack of data rich models that provide interpretable granular ward level solutions to aid and assist city planners.

**2.1 Lack of granularity** – Existing applications provide solution at a country, state or at a city level not at a ward level.

**2.2 Interpretability** – solutions do not provide quantified interpretable outputs.

**2.3 Data segregation** –data generated by the smart cities are in silos.

- Anita et al. studied the scope and opportunity in Pune to **understand the green cover** for maintaining a balanced floral diversity.
- National Research Development Corporation studied the **air quality** in Pune to develop an air information response plan.
- Morani et al. provide a **planting index** for a location by analyzing the associated tree cover. (Uses Geographic Information System (GIS) based visual approximation techniques to estimate the green tree cover.
- Shubham et al. studied the **effect of restricted emissions** during COVID-19 on air quality in India.
- Clement et al. studied and evaluated the **impact of some selected demographic and environmental variables** to identify potential risk areas and hotspots for COVID-19 transmission in Nigeria.

A novel data-driven approach which **aggregates** relevant data sources, creates data rich models to provide **granular ward level** insights and interpretable **scores** to improve the overall **health and living conditions in the cities.**

**4.1** Combining and utilizing rich feature set to provide **granular** ward-wise environmental health scores and recommendations.

**4.2** Investigating the environmental attributes, their trends and variations during the COVID-19 pandemic.

**4.3 Aggregated** data rich models that provides dynamic ward level risk scores.

### PROBLEM

Increased urbanization is causing **deterioration of environment** and living conditions.

### PROPOSED SOLUTION

Provides an **insight** and **recommendation** system that helps city planner take **data driven decisions** to improve cities and to enforce smarter policies. Our system provides,

- Insights related to the trees, population and air quality at the ward level.
- Ward wise environmental health score.
- Recommendations for creating green buffer zones around user specified locations to promote planting trees and help counter the urbanization effects.

Data

Tree Census

Air Quality Index

Population Census

$$Health\_Score = (Tree\_Score * 30) + (AQI\_Score * 40) + (Population\_Score * 30) \dots [1]$$

$$Tree\_Score = \frac{\sum_{i=1}^n Tree\_Value(i)}{Ideal\_Tree\_Score} \dots [2]$$

$$Ideal\_Tree\_Score = Max\_Tree\_Score * Ward\_Population * 7 \dots [3]$$

$$Tree\_Value = w1(Height) + w2(Canopy) + w3(Phenology) + w4(Condition) \dots [4]$$

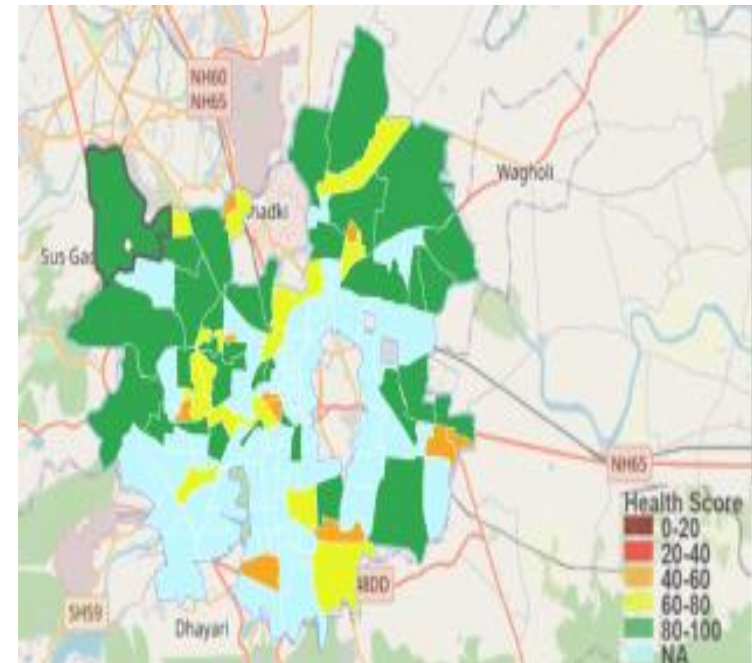

Figure 1. Ward Health Scores

**Green Buffer Zone Recommendation** to improve the green cover of a selected place based on its calculated health score.

1. Select location and radius.
2. Compute Health Score.
3. Provide **Recommendations:**

(Threshold : 80)

if (health score < 80)

then: provide recommendation to  
plant trees.

else,

Ward is healthy.

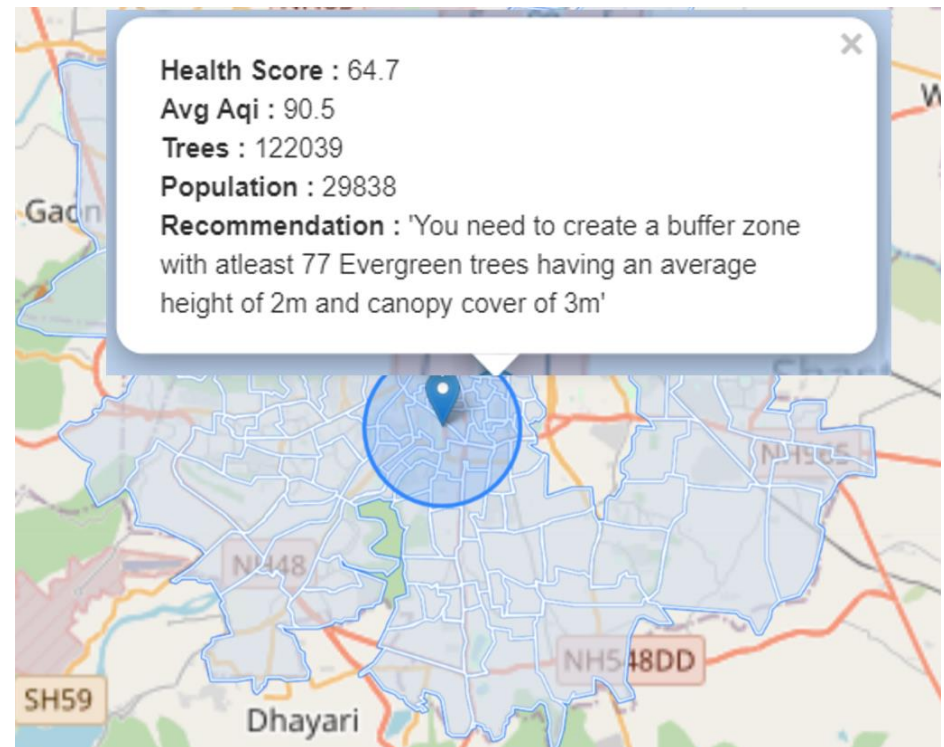

Figure 2. Green Buffer Zone Recommendation

## 4.2. Attribute Variations and Trends

Studied variations and trends in AQI, sound levels and individual pollutants across wards in Pune (Period : Jan 2020 to April 2021 )

- AQI levels decreased by 41.0%
- Sound levels (dB) decreased by 3.0%
- Ozone levels increased by 77.5%
- PM2.5 levels decrease by 83.7%
- PM10 levels decrease by 70.3%
- No2 levels decrease by 82.5%

Attribute: AQI ▾

Attribute Trends

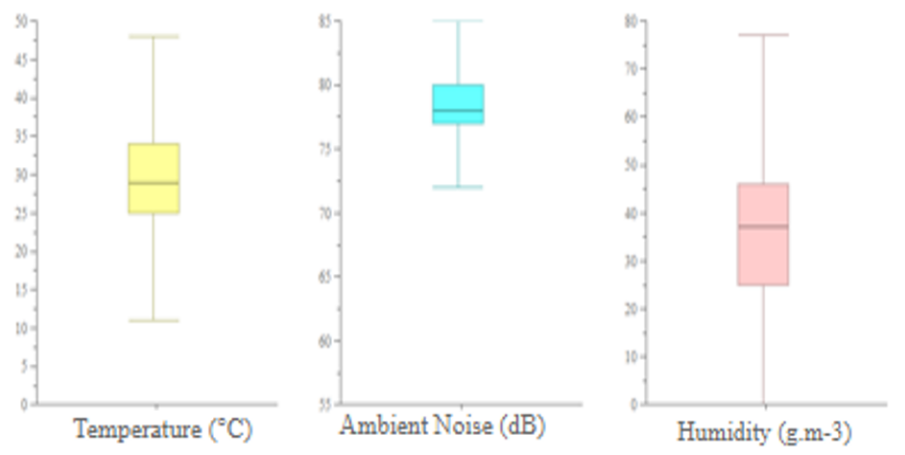

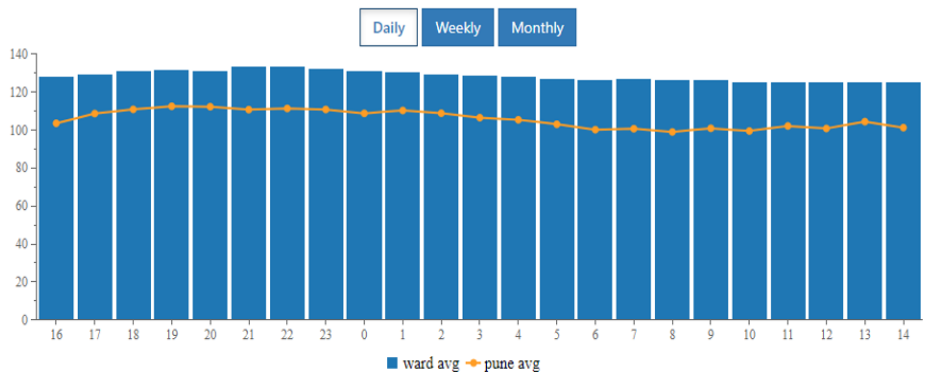

Figure 5. Pune-PMC Ward level Environmental parameter trend

### Background:

The unprecedented event of COVID 19 has put enormous amount of responsibility and pressure on city/town administrators and utilities to **improve** the existing **healthcare facilities**.

### Proposed solution

- Assess the overall health and infrastructure facilities available at ward level to **indicate the current risk**.
- **Formulate** it as **risk** score and provide **ward specific insights**.
- **Categorize wards** into critical, moderate and low risk zones.
- Help take **prioritized actions** for **ward planning** and further development.

- **COVID hospitals and bed details:** list of hospitals and #beds allocated to treat COVID-19 patients updated on a day-to-day basis.
- **Additional hospitals:** list of additional healthcare facilities and beds available in PMC-Pune region.
- **Demographics:** Publicly available information like - number of literates, number of children below age 6, working population and average family size.
- **Hotspots:** COVID-19 containment zones in PMC-Pune.
- **Environmental health scores:** AQI, tree and population count based Health Score.

## 4.3.2 Risk Assessment score formulation

- Number of active cases in the ward can be an indicator of ward risk.
- Risk score of a ward is highly correlated to Active Patients in a ward.

$$\begin{aligned} Risk\_Sum = & 0.1 * (Patients\ without\ oxygen) \\ & + 0.2 * (Patients\ with\ oxygen) \\ & + 0.3 * (Patients\ without\ ventilator) \\ & + 0.4 * (Patients\ with\ ventilator) \end{aligned}$$

...[6]

$$Initial\_RAS = \frac{Risk\_Sum}{Ward\_Population}$$

...[7]

- Studied feature correlation with active patients and selected relevant features. Selected features and historical data was used to train the model.

| Feature# | Feature Name                |
|----------|-----------------------------|
| 1        | Health Score                |
| 2        | Houses                      |
| 3        | Literate Population         |
| 4        | Population under 6          |
| 5        | Family Size                 |
| 6        | Working Population          |
| 7        | Hospitals                   |
| 8        | Oxygen beds                 |
| 9        | Beds without oxygen         |
| 10       | ICU ventilator beds         |
| 11       | ICU beds without ventilator |
| 12       | Additional beds             |
| 13       | Hotspots                    |

- Different algorithms were used to predict the Risk Assessment Score (RAS) and Gradient boosting was selected.

**TABLE IV**

PREDICTION ERRORS WITH MACHINE LEARNING MODELS: LINEAR REGRESSION (LR), K-NEAREST NEIGHBORS (KNN), RANDOM FOREST (RF), GRADIENT TREE BOOSTING (GTB)

| <b>Dates</b>         | <b>LR</b>    | <b>KNN</b>  | <b>RF</b>   | <b>GTB</b>  |

| Baner-Balewadi                | 81.9          | 599              |

\*per 10000 population.

- The predicted risk scores of previous day highly correlate to indicate the active patients of the current day.

# 4.3.3 Visualization – Risk Assessment

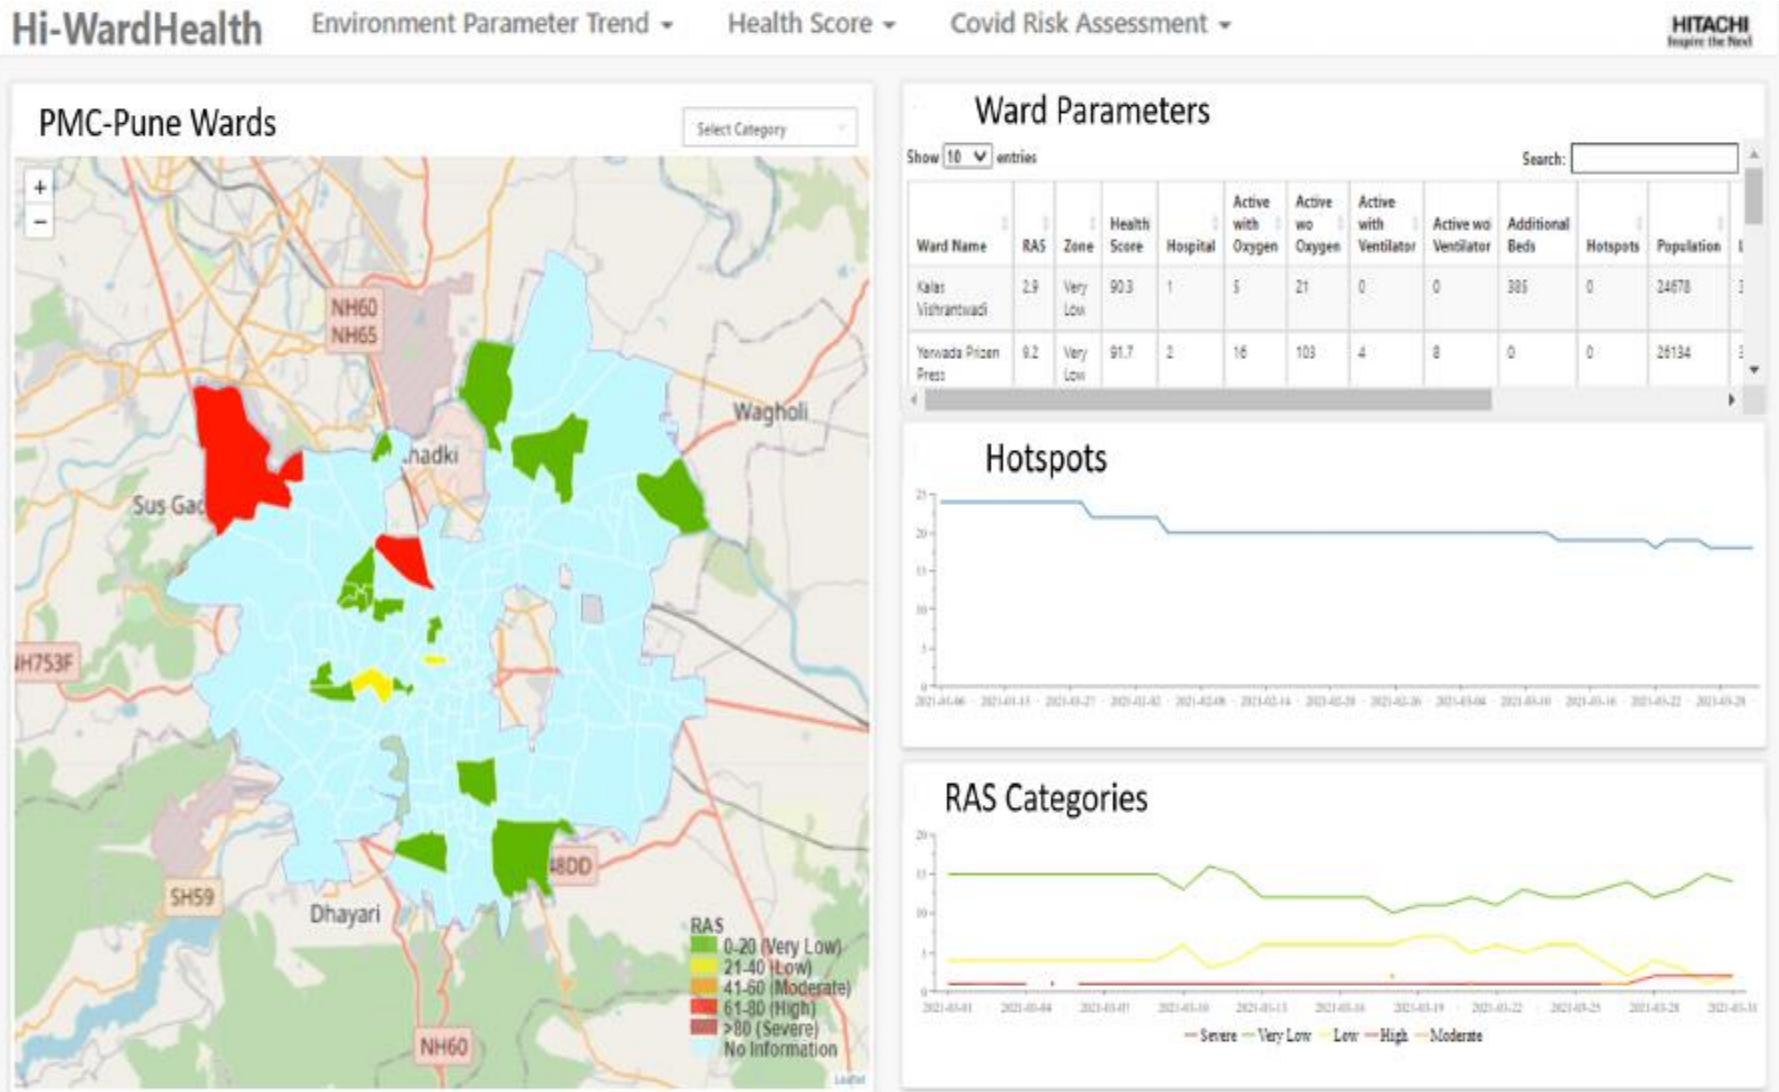

Figure 6. Pune-PMC COVID-19 Risk Assessment Scores

# 4.3.3 Visualization – Ward level Risk Assessment

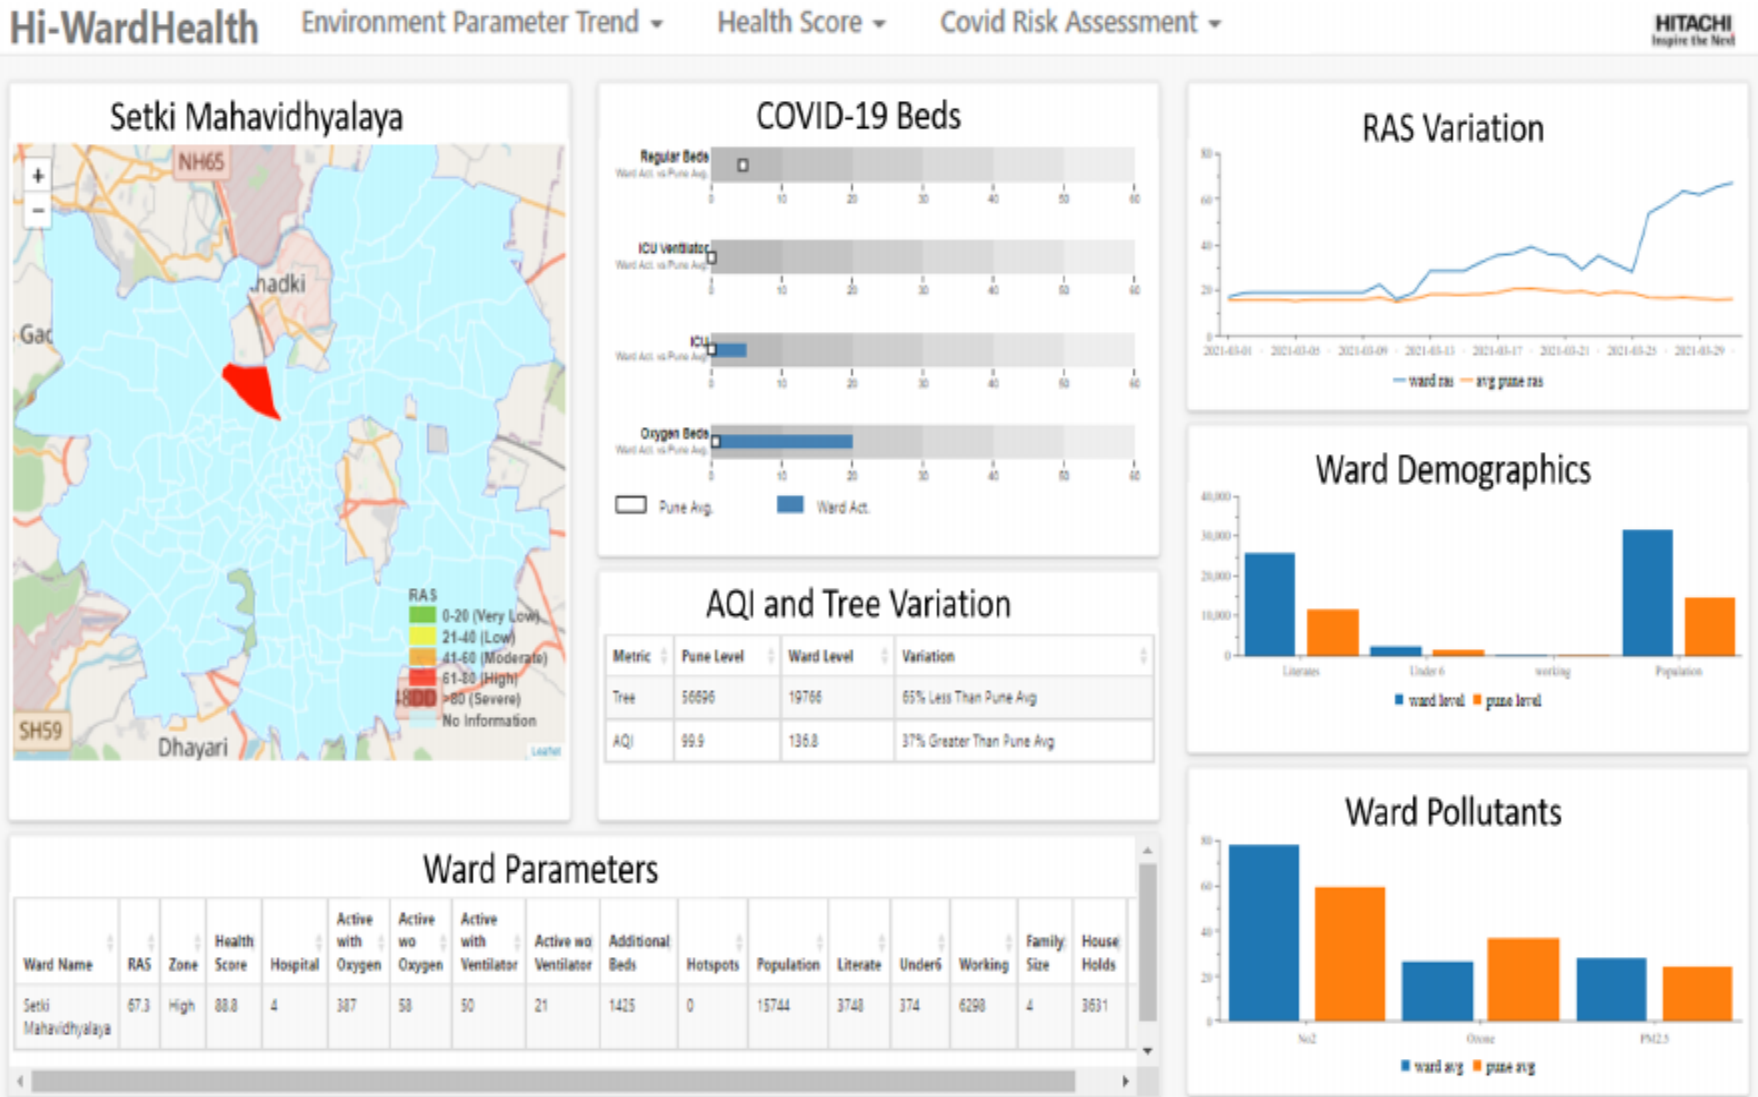

Figure 7. Pune-PMC Ward level COVID-19 Risk Assessment Score

- Health scores were derived for 63 wards.  
(AQI: 33 sensors, Tree data: 73 wards, Population census:144 wards.)
- Out of the 63 wards, 12 showed moderate, 15 satisfactory and 36 showed good health scores.
- Recommendations to improve green cover of an area is provided
- Environmental parameters and pollutant concentrations changed significantly during the lockdown.
- COVID-19 risk assessment scores were calculated for over 20 wards and categorized into risk zones.
- Detailed ward level analysis for the environmental and medical infrastructure facilities is provided.

- Dynamic numerical scores help understand the relative ward behaviour.
- Environmental health scores help improve the green cover of a place in the long run.
- Risk assessment scores can help authorities prioritize wards and plan actions. (Improving #beds, planning vaccination drive so on.)
- When the overall condition of a ward improves, its ability to handle situations like the pandemic increases.
- Additional features can improve the risk score formulation. ( Average hospitalization duration of patients, number of direct contacts, COVID-19 transmission related information etc.)
- Interpretations of visualizations can be further enhanced with Human Computer Interaction techniques.
- Work can be extended to other smart cities where similar data is available.
